

Based on IEC 60401, the data specified here are typical data for the material in question, which have been determined principally on the basis of toroids (ring cores).

The purpose of such characteristic material data is to provide the user with improved means for comparing different materials.

There is no direct relationship between characteristic material data and the data measured using other core shapes and/or core sizes made of the same material. In the absence of further agreements with the manufacturer, only those specifications given for the core shape and/or core size in question are binding.

4 Specific material data

DC magnetic bias

$$H_{-} = \frac{I_{-} \cdot N}{l_{e}}$$

H_{-} = DC field strength [A/m]
 I_{-} = Direct current [A]
 N = Number of turns
 l_{e} = Effective magnetic path length [m]

The curves of $\mu_{\text{rev}} = f(H_{-})$ allow an approximate calculation of the variation in reversible permeability (μ_{rev}) and A_L value caused by magnetic bias. These curves are of particular interest for cores for transformers and chokes, since magnetic bias should be avoided if possible with inductors requiring high stability (filter inductors etc.). In the case of geometrically similar cores (i.e. in particular the same A_{min}/A_e ratio) the effective permeability of the core in question in conjunction with the given curves suffices to determine the reversible permeability to a close approximation.

Relative loss factor versus frequency

(measured with ring cores, measuring flux density $\hat{B} \leq 0,25 \text{ mT}$)

Relative inductance component versus frequency
 (measured with ring cores, measuring flux density $\hat{B} \leq 0,25$ mT)

Performance factor versus frequency
